

The plots:

These plots indicate code puncturing rate $\frac{1}{2}$ and error probability, for p in range $0.0001 \rightarrow 0.2$

These plots indicate code puncturing rate $\frac{2}{3}$ and error probability, for p in range $0.0001 \rightarrow 0.2$

These plots indicate code puncturing rate 4/5 and error probability, for p in range $0.0001 \rightarrow 0.2$

These plots indicate code puncturing rate 4/7 and error probability, for p in range $0.0001 \rightarrow 0.2$

These plots indicate code puncturing rate $8/9$ and error probability, for p in range $0.0001 \rightarrow 0.2$

If you observed closely you would notice that the error probability for all rates have the same behavior (the error probability increases as the values of p increase) and for the throughput for all rates have the same behavior (the throughput decreases as the values of p increase).

As the code rate starts increasing in value for example the rate goes from $4/7$ to $8/9$, it makes a faster increase in the error probability and faster decaying in the throughput (the inclination gets bigger either the inclination is increasing or decreasing and the rate of change changes faster).
